**To:** Examiner Edward  
Johnson

**Date:** December 7, 2004

**Fax #:** 703-872-9306

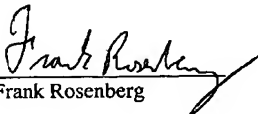

**Pages:** 6, including this cover sheet.

**From:** Frank Rosenberg

**Subject:** Comparison with Prior Art  
Serial No. 10/076,880

Dear Examiner Johnson,

Thank you for finding the time for an interview on such short notice. We appreciate your exceptional efforts to assist the applicants. Attached with this fax is a comparison with the cited Wieland reference. We will call you at 2 PM, Wednesday Dec. 8 for the interview to discuss this comparison.

  
Frank Rosenberg

## Comparison of MeOH Steam Reforming Catalyst with U.S. Patent 6,413,449

### 1. Analysis of Relevant Information from U.S. Patent 6,413,449

a) In Wieland's patent, conversion of MeOH is not given. They report catalyst performance based on CO<sub>2</sub> selectivity and hydrogen productivity. In the patent, CO<sub>2</sub> selectivity is defined as  $S_{CO_2} = P_{CO_2} / (P_{CO_2} + P_{CO})$ , hydrogen productivity is defined as  $P_{cat} = V_{H_2} / M_{cat} \cdot t [Nm^3 / kg_{cat} \cdot h]$ .

b) Because of high CO<sub>2</sub> selectivity is obtained, steam reforming reaction is dominate:  
 $CH_3OH + H_2O \rightarrow 3 H_2 + CO_2$   
This means, when 1 mol methanol is converted, 3 mol of hydrogen will be produced.

c) On page 8 of the patent, it is indicated that catalysts are all examined at LHSV=5 h<sup>-1</sup> (total LHSV=8.3 h<sup>-1</sup>) which is equivalent to 5 ml MeOH/ml catalyst. h. Based on this number, the maximum H<sub>2</sub> productivity per volume of catalyst per hour can be calculated as follow:

Maximum H<sub>2</sub> productivity=5 (ml MeOH/ml catalyst. h) x 0.791 (g/ml) / 32 (g/mol) \* 3 (mol H<sub>2</sub>) \* 22414 ml = 8310 ml/ml catalyst. h.

This is the H<sub>2</sub> productivity at 100% MeOH conversion

### 2. Performance Comparison

In order to make a fair comparison on catalyst performance, we should express hydrogen productivity on per catalyst volume basis (H<sub>2</sub>/ml catalyst. h), not on weight basis. This is because the volume of catalyst is important in determining the efficiency of reformer. The productivity based on weight of catalyst or weight of Pd can only be used for kinetic study but may not precisely reflect efficiency of reformer, especially when catalysts of different density are compared. The following comparisons are made by assuming the best scenario for Wieland's patent.

*From Wieland's Patent:*

As shown in Table 1 of Example 1, on raising temperature from 300 to 400°C, the hydrogen productivity continues to increase. This implies that at 300°C, the conversion is not 100%. As a result, we can calculate the best scenario by assuming that 100% conversion is reached at 400°C. That means, at 300°C, only 57% MeOH conversion is obtained (37.8/66.2=57%, data from column 4 of Table 1).

Therefore, productivity of H<sub>2</sub> at 300°C= 0.57 \* Maximum Productivity=4737 ml/ ml catalyst. h.

*From Our Patent Application:*

As shown in Attached Table, at 284°C and LHSV=30.5 h<sup>-1</sup>, methanol conversion of 99.9 % and hydrogen productivity of 29,000 ml/ ml catalyst. h are obtained, respectively. This clearly indicates that higher productivity achieved on our catalyst is not simply caused by operating at high throughput, otherwise we will not achieve 100% conversion. It is because the unique catalytic properties, allowing to operate at high turn over rate to achieve high productivity.

In fact, to compare our catalyst at 100% conversion with Wieland's at 57% conversion has put us in unfavorable conditions. The following is an exercise to compare our catalyst with the U.S. patent at the same methanol of conversion level of 57%. We know from Table 1 that, at 284°C and LHSV=30.5 h<sup>-1</sup>, 99.9% conversion is achieved. By pushing the feed rate up (increase LHSV), conversion is going to decrease. The question is, at what LHSV, 57% conversion is going to be achieved. By assuming first order kinetics, which is commonly accepted for steam reforming reaction, we have calculated that feed rate should be increased to LHSV=249.6 h<sup>-1</sup> in order to reach 57% conversion (See Appendix).

At LHSV=249.6 h<sup>-1</sup>, and 57% conversion, hydrogen productivity is 131,400 ml/ml catalyst. h, this is even higher than what we reported at 100% conversion (29,000 ml/ml catalyst. h)

In conclusion, our powder catalyst is much more active than those mentioned in Wieland's patent.

*Wieland's Catalyst Hydrogen Productivity at 150ms.*

First we need to calculate  $WHSV_{MeOH}$  at 150 ms, then use first order kinetics to calculate MeOH conversion at this contact time, and hydrogen productivity will be easy to calculate.

150ms is equivalent to total GHSV=24,000h<sup>-1</sup>, which is total feed rate of 24,000 ml/ml catalyst.h.

This can be converted into total feed rate of 1.071 mol /ml catalyst. h . (24000/22400).

Because  $H_2O/MeOH = 1.5$  (mol/mol), the above feed rate is equivalent to : (0.43 mol MeOH +0.641 mol H<sub>2</sub>O)/ml cat. H.

So, at 150 ms, MeOH feed rate:  $WHSV_{MeOH} = 0.43$  mol/ml cat.h=13.76 g/ml cat.h.

As discussed in the previous section, at 300°C, LHSV=5 h<sup>-1</sup> ( $WHSV_{MeOH} = 3.95$  g/ ml cat.h), conversion of Wieland catalyst is 57%. Then, what is the conversion at  $WHSV_{MeOH} = 13.76$  g/ ml cat.h ?

Using the first order kinetics listed in Appendix, we obtained conversion=22%,  
Therefore, hydrogen productivity at 150ms=  $13.76/32 * 0.22 \times 3 \times 22400 = 6360$  ml/mlcat.h

Table 1. Comparison of Velocys MeOH SR Catalyst with U.S. Patent 6,413,449

Characteristics and Performance	Velocys' SR Catalyst		U.S. Patent 6,413,449
	Engineer	Powder	
Composition of Active Component, wt%			
Al <sub>2</sub> O <sub>3</sub>	60-80	60-80	70-80
ZnO	10-30	10-30	10-20
Pd	10	10	1-5
Engineered Supports	FrCrAlY Felt	None	Ceramic Honeycomb
Method of Making Active component Pd/ZnO/Al <sub>2</sub> O <sub>3</sub>	Precipitation of Zn on Al <sub>2</sub> O <sub>3</sub> then impregnate Pd. Wash-coat on felt	Precipitation of Zn on Al <sub>2</sub> O <sub>3</sub> then impregnate Pd	Impregnate Zn and Pd simultaneously on Al <sub>2</sub> O <sub>3</sub> coated on ceramic Honeycomb
Testing Conditions			
P, atm	1	1	1
T, °C	300	284	300
LHSV, h <sup>-1</sup>	130	30.5	8.3 (5 for MeOH only)
Conversion of MeOH	82%	99.9%	57% (Assuming 100% conversion at 400°C)
Productivity, ml H <sub>2</sub> /ml catalyst .h	90,000	29,000	4,737
